■ drand - A Distributed Randomness Beacon

- Write your own oracle
- League of Entropy
 - “first time ever that a randomness beacon is run by several organizations”
 - “Every other existing randomness beacon is generated by an individual entity”, e.g. random.org

■ **04.11.2019** Bitcoin (BTC) 2017 Rally Caused by Single Whale, Research Shows

- The series of \$1,000 days that brought BTC to a record above \$19,600 could have been the work of one entity
- “price action was happening on a single exchange, and seemingly from a single account.”
- Bloomberg: “The idea that a lone whale fueled a yearlong Bitcoin bull run is a little silly “

■ **04.11.2019** Ethereum (ETH) Pushes Back Mining Freeze Once Again

- The Berlin hard fork will probably be used to code another delay for the mining ice age.
- Q: ice age?

■ **02.11.2019** Bitcoin, 11-years in

- Another point of view

■ **05.11.2019** Facebook Libra is Architecturally Unsound

- “Libra’s byzantine tolerance on a permissioned network is an incoherent design.”
 - The algorithm chosen by Libra still has a worst-case $O(n^2)$ communication
- TPS, Move language, Ed25519, consumer protection, [reply](#)

Distributed Systems - In the News

■ 4.11.2019 Building a Large-scale Distributed Storage System Based on Raft

- TiKV, a large-scale open source distributed database based on Raft
- Extended Raft with Regions
- [Github](#), ACID, Rust
- Sharding: Data distribution of HDFS DataNode (see lecture 7, slide 36)
- Other examples of consistent hashing?

http://energystudy.synergylabs.org/courses/15-440-Fall2017/lectures/16-gfs_hdfs_spanner.pdf

■ 01.11.2019 [DNS Wars](#)

- DNS is fundamental part of the infrastructure of the Internet
- Distributed database
- Initial distribution of names was via flooding of a common copy of the hosts file
 - Scalability?
- First DNS War was fought over the transition of DNS names in .com, .net and .org
 - Free → Network Solutions (monopoly)
 - Finally: competition in name registration services
- Sitefinder
 - Wildcard for domain names that did not exist → redirect to search engine

- Akamai CDN, delivered result based on how close DNS resolver was
 - 8.8.8.8?
 - [Extension mechanisms for DNS](#)
 - “EDNS is also used for sending general information from resolvers to name servers about clients' geographic location in the form of the EDNS Client Subnet (ECS) option”
 - It destroys DNS privacy
- Today's [DoH/DoT](#) Wars
 - DNS over TLS/TCP
 - DNS over HTTPS
 - Why DoH at all? It doesn't appear to be solving a technology or a performance issue that is not already competently addressed in DoT – DoT/853 vs DoH/443, push DoH
 - Mozilla announced [DoH to Cloudflare's Open Recursive Resolver](#)

Challenge Task

■ Today deadline milestone

06.11.2018 - 23:59

- 18 students on unterricht.hsr.ch, 14 students doing the challenge task on dsl.hsr.ch

■ Exam of last year online: dsl.hsr.ch

Aufgabe 5: Blockchains (12 Punkte)

Dieser Smart Contract hält in der Variable **balances** fest, welche Adresse wie viele Tokens hat. Die Funktion **dividend()** zahlt jeder Adresse einen Token aus.

```
pragma solidity ^0.4.25;

contract Exam {
    address private owner;
    mapping (address => uint256) private balances;
    address[] private balances_keys;

    constructor() {
        owner = msg.sender;
    }

    function dividend() public {
        require(owner == msg.sender);
        for(uint256 i=0;i<balances_keys.length;i++) {
            balances[balances_keys[i]] = balances[balances_keys[i]] + 1;
        }
    }
}
```

a) (4P) Was ist das Problem in der Funktion **dividend()**

b) (4P) Bei einem ICO, welcher einen ERC-20 Token heraus gibt, könnte der Token direkt nach der Überweisung von Ethers an einem Smart Contract erstellt werden. Was ist der Nachteil für den Benutzer/Investor wenn man einen Token direkt erstellt?

c) (4P) Sie entwickeln eine eigene Blockchain mit PoW. Sie wissen, dass ein Miner 1.067 H/s leisten kann. Sie möchten, dass ein Miner in einer Minute alle Varianten mit der Nonce durchrechnen kann. Wie viele Bits muss die Nonce haben? (Hinweis: die Anzahl Bits ist ganzzahlig)

Consensus (last weeks lecture)

- **Definition:** Consensus decision-making is a group decision-making process in which group members develop, and agree to support a decision **in the best interest of the whole**.
- A Byzantine fault is an arbitrary fault that occurs during the execution of an algorithm by a distributed system
 - Not only crash, but lie or even collude to reach an advantage
- Your own nodes, your control, no collusion
- Other forms of consensus
 - Paxos
 - Raft
 - vDHT

- **Often: consensus defines leader**

- Leader creates block,
- Leader adds data
- Leader creates version

- **How to find a leader?**

[source](#)

Paxos History

- **Leslie Lamport** discovered the Paxos algorithm in late 1980s
 - Attempt to prove that there was no such algorithm which can tolerate the failure of any number of its processes
 - Until he realized that he created working protocol

[source](#)

- Wrote paper and submitted it to Transactions on Computer Systems (TOCS) in 1990
 - Reviewer: was mildly interesting, but needs significant improvement
 - Leslie Lamport: “so I did nothing with the paper”
- People started to using Paxos to solve problems in distributed systems
- Resubmitted in 1998 to TOCS
 - Accepted without any major changes
- Paxos paper won an ACM SIGOPS Hall of Fame Award in 2012
- **Received Turing award in 2013**, also due to Paxos
 - “Turing Award is generally recognized as the highest distinction in computer science and the “Nobel Prize of computing””

Paxos consensus

■ Paxos: considered difficult to understand

- [“This website explains the infamously difficult to understand Paxos consensus protocol”](#)
- [“Paxos, a really beautiful protocol for distributed consensus”](#)
- [“Paxos is an algorithm whose entire behaviour is subtly difficult to grasp”](#)

■ Problem: want reliable computing,

- But: have unreliable components

■ Due to unreliable components, run multiple components, i.e, multiple servers

- Replica: inconsistent state

■ Paxos guarantees that nodes will only ever choose a single value, but does not guarantee that a value will be chosen if a majority of nodes are unavailable

■ Roles: proposer, acceptor, and learner

- Proposer proposes a value that it wants agreement upon
- Acceptor gets proposal, makes promises, sends result to learners
- Learners: majority of acceptors must choose the same value

■ 2 phases: prepare/promise phase, accept phase

Paxos consensus

- **Proposer: prepare and accept requests, proposal number and value (n, v)**

- Acceptor: already seen higher proposal number: ignore
- Acceptor: seen lower proposal number: send back highest accepted n,v.

- **Proposer A and proposer B**

- Acceptor Z receives B before A

- **If acceptor receiving a prepare request for the first time**

- Acceptor responds with a prepare response
- Promises never to accept another proposal with a lower proposal number

Paxos consensus

- **Acceptor Z receives proposer A's request, and acceptors X and Y receive proposer B's request.**
 - Only accept requests with higher number, Acceptor Z not sending response (or negative response) to B.
- **Proposer B sends an accept request to each acceptor containing the proposal number it previously used (n=4) and the value associated with the highest proposal number among the prepare response messages it received (v=8)**
- **Proposer A sends its accept request before proposer B, but acceptor ignores them**

Paxos consensus

- If an acceptor receives an accept request for a higher or equal proposal number than it has already seen, it accepts and sends a notification to every learner node.
 - A value is chosen by the Paxos algorithm when a learner discovers that a majority of acceptors have accepted a value
 - Once a value is chosen by Paxos, communication with other proposers cannot change value
 - If another proposer, sends a higher proposal number than has previously been seen, with a different value (e.g., $n=6, v=7$), each acceptor responds with the previous highest proposal ($n=4, v=8$)
 - This requires the proposer to send an accept request containing $[n=6, v=8]$, which confirms the value that has already been chosen

- **Leader election: the leader is the node that has its data chosen by the Paxos instance**

Raft (multi paxos)

- “this makes Raft more understandable than Paxos and also provides a better foundation for building practical systems.”
- **RAFT: Reliable, Replicated, Redundant, And Fault-Tolerant**
- **Follower, Candidate, Leader**
 - Raft implements leadership election,
 - Once a leader has been elected, all decision-making within the protocol will then be driven only by the leader
 - Only one leader can exist at a single time
- Each follower has a timeout (typically between 150 and 300 ms) in which it expects the heartbeat from the leader.
 - The system is only available when a leader has been elected and is alive
 - Otherwise, a new leader will be elected and the system will remain unavailable for the duration of the vote
 - Starts election by increasing term counter, voting for itself, and sending a message to all other servers requesting their vote
 - If a higher term is received, become follower, if not, leader

Consistency

■ Consistency in DHTs – vDHT, similarities to Paxos

- Number = versions, for doing updates
- Simplified roles (peer)
- No leader election, works well with churn (not heavy churn)

■ CoW, software transactional memory (STM) → for consistent updates. Works for light churn

■ vDHT Basics

- No locking, no timestamps
- Every update – new version
 - 1. get() latest version, check if all replica peers have latest version, if not wait and try again
 - may add delay
 - + wait until update is completed
 - 2. put() prepared with data and short TTL, if status is OK on all replica peers, go ahead, otherwise, remove the data and go to step 1.
 - Data can be either send now or with the confirm, if sent now we are optimistic
 - Peer marks the value as prepared, other put() fail on that key. If nothing happens, TTL
 - Value linked to previous version(s) (hash)

- 3. put() confirmed, don't send the data, just remove the prepared flag and reset TTL

■ In case of heavy churn, API user needs to resolve

- Get latest version may return fork
- Abort or resolve (join) manually

Room: HSR

Kademlia Broadcasting / Flooding in P2P

■ Flooding scales poorly

- Unnecessary traffic
- 5 peers, fully meshed: 4 msg, 4 x 3 msg → 16 msg

■ Reduce Messages

- Don't send to all neighbors ([random walk](#))
- [Coupon collector's problem](#)
 - Number of trials grow $O(n \log n)$,
 - Reach 50 peers, it takes about 225 trials to reach all 50 peers
 - Tradeoff: all peers vs. most peers / many msgs vs. reduce msgs

■ Broadcasting use-cases

- Broadcast global parameters, global events (maintenance)
- Hierarchical system: broadcast root inode (e.g. / in a file system)
- Send message to all players (challenge task)

■ Ethereum Wispher: TTL, “probabilistic message forwarding”

Broadcasting in Structured Systems

- 5 peers fully meshed: How to send only 4 messages?

- Structured vs. unstructured:

- Knowing the direction

- Broadcasting in ring-based Overlay

- Main idea: tell other peers in what direction so send

- Example:

- Send to neighbor (successor)
- For faster spreading / redundancy send to far away peer (overhead)
- Overhead: 4 messages

- Kademlia? Tree-based structure

Broadcasting in Kademlia

- Tree structure – no direction, example 7 peers
- Main idea: send to random peer in bag X
 - Send along in which bag this peer was, only send to smaller bags

Peer 6 (110) broadcast to b1,b2,b3

7 (b1)	4 (or 5) (b2)	0 (or 1, 2) (b3)
--------	---------------	------------------

Peer 4 (100) broadcast to b1

5 (b1)	- 6	- 0
--------	-----	-----

Peer 0 (000) broadcast to b1,b2

1 (b1)	2 (b2)	- 6
--------	--------	-----

- Peer 4 and 0 send simultaneously

Broadcasting in Kademlia

- **7 peers, 6 messages**
 - Works only with perfect routing, churn?
- **Redundancy: send to R random peer in bag X**
 - Previous example: R=1, TomP2P: R=3
- **Demo: StructuredBroadcastHandler**
 - 1000 peers
 - FROM_EACH_BAG = 3, ~3800 messages
 - No redundancy: 999 messages
- **Testcase/showcase:**
 - `net.tomp2p.p2p.TestBroadcast.testBroadcastTCP()`

The logo for TomP2P, featuring the text "TomP2P" in a bold, white, sans-serif font against a blue sky background with white clouds.

Protocol, Serialization, VSS recap: Layer 4 - TCP

■ Connection establishment

- SYN, SYN-ACK, ACK (three way)
- Initiates TCP session: initial sequence number is ~[random](#)
- [Congestion control](#)

■ Connection termination

- FIN, ACK + FIN, ACK (three/four way)
- 3-way handshake, when host 1 sends a FIN and host 2 replies with a FIN & ACK

■ Sequences and ACKs

- Identification each byte of data
- Order of the bytes → reconstruction
- Detecting lost data: RTO, DupACK:

■ Retransmission timeout

- If no ACK is received after timeout (e.g. 2xRTT), resend.

■ Duplicate cumulative acknowledgements

- ACKs for last consecutive packets
- 3 times same ACK → retransmit (fast retransmit)

■ Security: Transport Layer Security (TLS)

1. "client hello" lists cryptographic information, TLS version, [ciphers/keys](#)
 - Forward secrecy: ephemeral keys
2. "server hello" chosen cipher, the session ID, random bytes, digital certificate (checked by client), optional: "client certificate request"
3. Key exchange using random bytes, now server and client can calc secret key
4. "finished" message, encrypted with the secret key

https://www.ibm.com/support/knowledgecenter/SSFKSJ_7.1.0/com.ibm.mq.doc/sy10660_.htm

Protocol considerations

- Ping to Australia: 329ms
 - One way ~ 165ms
- TCP + TLS handshake:
 - 3RTT = 987ms! No data sent yet
- QUIC: 1RTT, TLS 1.3: 2RTT

- Block time Bitcoin 10min
- Blockchains today 60s – 0.5s ([tomo](https://twitter.com/thecryptowoman/status/1021385599088054273))
